Random Variable

An **aspect of the problem domain** which we **may have uncertainty** about

Random Variable (RV)	Description	Domain (D)
D	Result from flipping a die	{1,2,3,4,5,6}
R	Raining?	{yes, no}
M	Winning a football match	{win, lose}

Explanation

Random Variable : Always capital letters

Domain : Small letters enclosed in `{ }` ; A list of possible values

Probability Distribution Table

Specifies the $P()$ of all the values (outcomes) for a given **RV**

Example

T	P(T)
hot	0.6
cold	0.4

Probability Rules

- \forall_x within the **RV**, $0 \leq P(x) \leq 1$
- Sum of all $P(x)$ is 1

Joint Distribution

A table specifying the $P()$ for multiple **RVs**

Probabilistic Model : joint distribution over a set of **RVs**

$W = \{hazy, sunny, rainy\}$

$T = \{hot, cold\}$

$P(T, W)$			
	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.25	0.3	0.05
<i>cold</i>	0.15	0.05	0.20

$P(T, W)$	
<i>hot, hazy</i>	0.25
<i>cold, hazy</i>	0.15
<i>hot, sunny</i>	0.30
<i>cold, sunny</i>	0.05
<i>hot, rainy</i>	0.05
<i>cold, rainy</i>	0.20

Note : The probability rules apply here too

Events

It is a **set** of outcomes for the **set of RV** (inferred from Joint Distributions)

Calculating Probability of an Event

Add up all the entries which are consistent with the event

$$P(E) = \sum_{x_1, x_2, \dots, x_n} P(x_1, x_2, \dots, x_n)$$

Example : Find the probability of hazy

$P(T, W)$			
	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.25	0.3	0.05
<i>cold</i>	0.15	0.05	0.20

$$\begin{aligned} P(hazy) &= P(hazy, hot) + P(hazy, cold) \\ &= 0.25 + 0.15 = 0.40 \end{aligned}$$

\wedge AND, \vee OR

Example Events

$$P(T, W)$$

	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.25	0.3	0.05
<i>cold</i>	0.15	0.05	0.20

- $P(\text{hot})?$ $0.25 + 0.3 + 0.05 = 0.6$
- $P(\neg \text{hazy})?$ $0.3 + 0.05 + 0.05 + 0.2 = 0.6$
- $P(\neg \text{hazy} \vee \text{cold})?$ $0.3 + 0.05 + 0.05 + 0.2 + 0.15 = 0.75$
- $P(\text{hot} \wedge \neg \text{sunny})?$ $0.25 + 0.05 = 0.30$
- $P(\text{hazy} \wedge \text{rainy})?$ **Not possible**

Marginal Distributions

Sub-tables which **eliminates** certain variables

The process of **summing out/marginalization** helps us extract the distribution over some subset of variables

Conditional Distributions

$P(W|T)$ is the probability of the weather given it is hot/cold

Example : Converting a joint distribution $P(W, T)$ to conditional

Suppose the **temperature** is **hot**:

Full joint distribution
 $P(T, W)$

	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.25	0.3	0.05
<i>cold</i>	0.15	0.05	0.20

Retain the entries conforming
to the given fact

Part of the
full joint distribution
 $P(T=\text{hot}, W)$

	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.25	0.3	0.05

Does not sum to 1. Not a
probability distribution.

/0.6

Normalize so
that it sum to 1

Conditional distribution
 $P(W | \text{hot})$

	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.42	0.5	0.08

Sums to 1. This is a
probability distribution.

$P(\text{hazy} | \text{hot})$

$P(\text{sunny} | \text{hot})$

$P(\text{rainy} | \text{hot})$

Product Rule

$$P(x, y) = P(x|y)P(y) \equiv P(x|y) = \frac{P(x,y)}{P(y)}$$

Using that,

Example:

	<i>hazy</i>	<i>sunny</i>	<i>rainy</i>
<i>hot</i>	0.25	0.3	0.05
<i>cold</i>	0.15	0.05	0.20

$$\begin{aligned} P(\text{hazy}) &= P(\text{hazy, hot}) + P(\text{hazy, cold}) \\ &= 0.25 + 0.15 = 0.4 \end{aligned}$$

$$\begin{aligned} P(\text{hot} | \text{hazy}) &= P(\text{hot, hazy}) / P(\text{hazy}) \\ &= 0.25 / 0.4 \\ &= 0.625 \end{aligned}$$

$$\begin{aligned} P(\text{hazy, hot}) &= P(\text{hot} | \text{hazy}) P(\text{hazy}) \\ &= 0.625 \times 0.4 \\ &= 0.25 \end{aligned}$$

Refer to Slide 17,18 Example 2 and 3

Probabilistic Inference

Compute a desired probability from other know probas (e.g conditional from joint)

Inference by enumeration

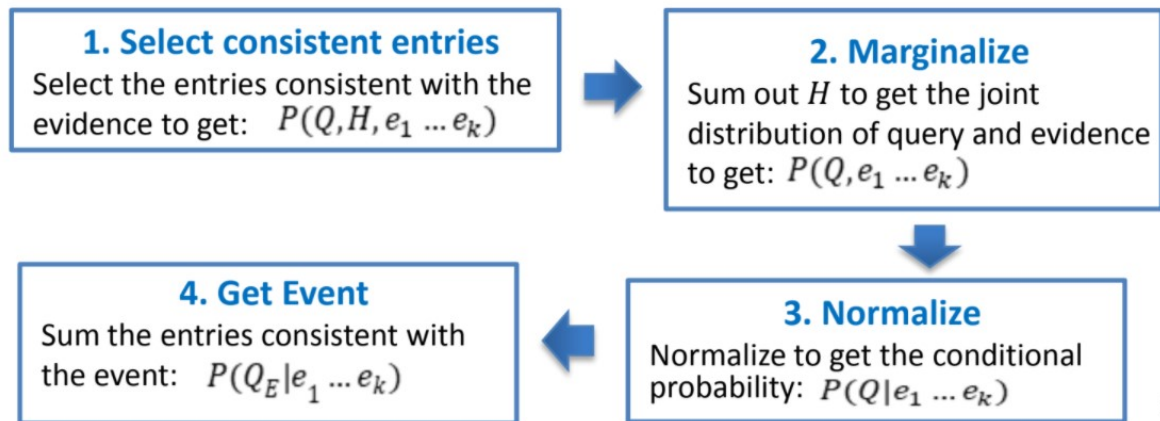

Given the following:

- Query event: Q_E
- Query variables: $Q = Q_1 \dots Q_p$
- Evidence variables: $E = E_1 \dots E_k = e_1 \dots e_k$
- Hidden variables: $H = H_1 \dots H_r$

and we want to find:

$$P(Q_E | e_1 \dots e_k)$$

The inference process:

2

Causal and Diagnostic Probability

Take Cause = Dengue, Effect = Fever

Usually we have $P(\text{Effect}|\text{Cause})$, **causal probability**

We want this $P(\text{Cause}|\text{Effect})$, **diagnostic probability**

So we need **Bayes Rule** to help us get the reverse

$$P(x|y) = \frac{P(y|x)P(x)}{P(y)} \text{ OR } P(\text{Cause}|\text{Effect}) = \frac{P(\text{Effect}|\text{Cause})P(\text{Cause})}{P(\text{Effect})}$$
